
Getting Started with ADC

Introduction

Author: Victor Berzan, Microchip Technology Inc.

The Analog-to-Digital Converter (ADC) peripheral converts an analog voltage to a numerical value. This peripheral is included in many AVR® microcontrollers (MCUs). A 10-bit single-ended ADC peripheral is available on most of the tinyAVR® and megaAVR® MCUs.

This technical brief describes how the Analog-to-Digital Converter module works on megaAVR® 0-series microcontrollers. It covers the following use cases:

- **ADC Single Conversion:**

Initialize the ADC, start conversion, wait until the conversion is done, read ADC result.

- **ADC Free Running:**

Initialize the ADC, enable Free Running mode, start conversion, wait until the conversion is done and read the ADC result in an infinite loop.

- **ADC Sample Accumulator:**

Initialize the ADC, enable accumulation of 64 samples, start conversion, wait until the conversion is done and read ADC result in a loop.

- **ADC Window Comparator:**

Initialize the ADC, set the conversion window comparator low threshold, enable the conversion Window mode, enable the Free Running mode, start the conversion, wait until the conversion is done and read the ADC result in an infinite loop, and light-up an LED if the ADC result is below the set threshold.

- **ADC Event Triggered:**

Initialize the ADC, initialize the Real Time Counter (RTC), configure the Event System (EVSYS) to trigger an ADC conversion on RTC overflow, toggle an LED after each ADC conversion.

Note: The code examples were developed on ATmega4809 Xplained Pro (ATMEGA4809-XPRO).

1. Relevant Devices

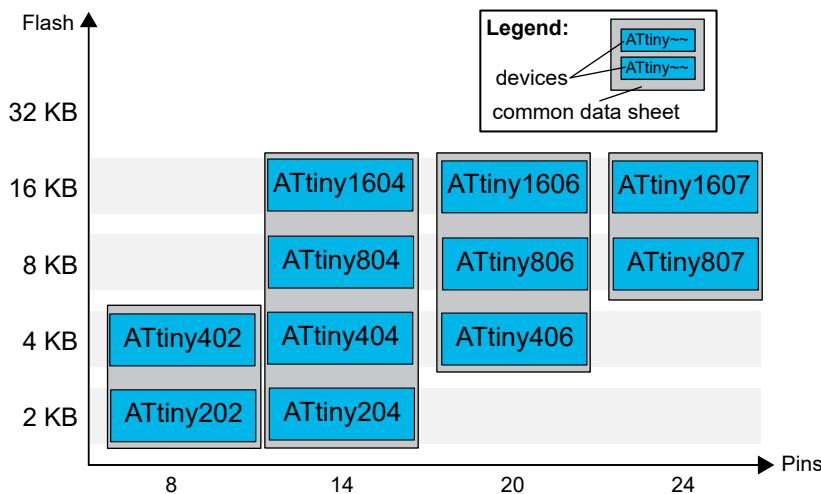

This chapter lists the relevant devices for this document.

1.1 tinyAVR® 0-series

The figure below shows the tinyAVR® 0-series, laying out pin count variants and memory sizes:

- Vertical migration is possible without code modification, as these devices are fully pin- and feature compatible.
- Horizontal migration to the left reduces the pin count and therefore, the available features.

Figure 1-1. tinyAVR® 0-series Overview

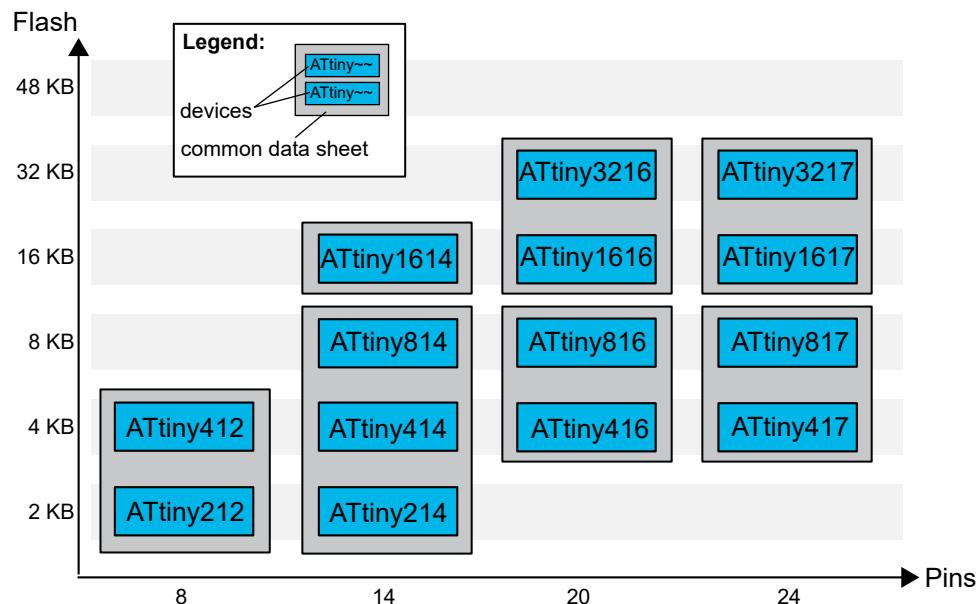

Devices with different Flash memory size typically also have different SRAM and EEPROM.

1.2 tinyAVR® 1-series

The figure below shows the tinyAVR® 1-series devices, laying out pin count variants and memory sizes:

- Vertical migration upwards is possible without code modification, as these devices are pin compatible and provide the same or more features. Downward migration may require code modification due to fewer available instances of some peripherals.
- Horizontal migration to the left reduces the pin count and therefore, the available features.

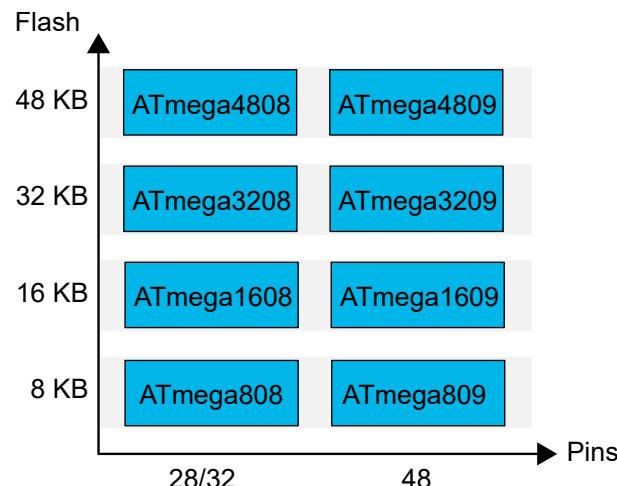

Figure 1-2. tinyAVR® 1-series Overview

Devices with different Flash memory size typically also have different SRAM and EEPROM.

1.3 megaAVR® 0-series

The figure below shows the megaAVR 0-series devices, laying out pin count variants and memory sizes:

- Vertical migration is possible without code modification, as these devices are fully pin and feature compatible.
- Horizontal migration to the left reduces the pin count and, therefore, the available features.

Figure 1-3. megaAVR® 0-series Overview

Devices with different Flash memory size typically also have different SRAM and EEPROM.

2. Overview

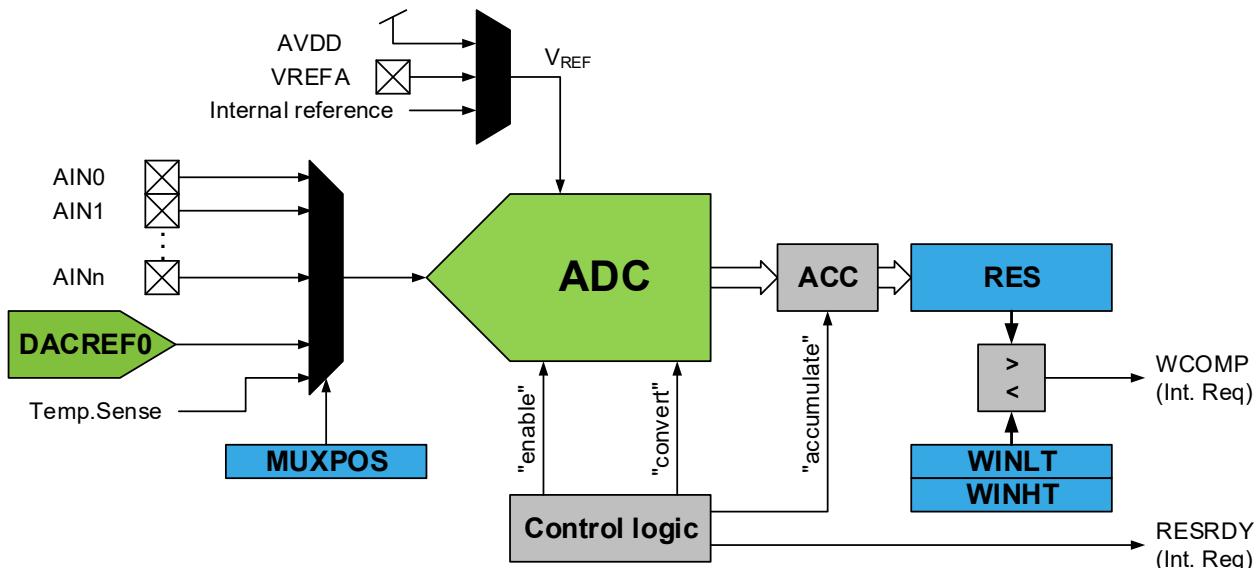

The Analog-to-Digital Converter (ADC) peripheral produces 10-bit results. The ADC input can either be internal (e.g. a voltage reference), or external through the analog input pins. The ADC is connected to an analog multiplexer, which allows selection of multiple single-ended voltage inputs. The single-ended voltage inputs refer to 0V (GND).

The ADC supports sampling in bursts where a configurable number of conversion results are accumulated into a single ADC result (Sample Accumulation). The ADC input signal is fed through a sample-and-hold circuit that ensures the input voltage to the ADC is held at a constant level during sampling.

Selectable voltage references from the internal Voltage Reference (V_{REF}) peripheral, V_{DD} supply voltage, or external V_{REF} pin (VREFA).

A window compare feature is available for monitoring the input signal and can be configured to only trigger an interrupt on user-defined thresholds for under, over, inside, or outside a window, with minimum software intervention required.

Figure 2-1. ADC Block Diagram

The analog input channel is selected by writing to the MUXPOS bits in the MUXPOS register (ADCn.MUXPOS). Any of the ADC input pins, GND, internal Voltage Reference (V_{REF}), or temperature sensor, can be selected as single-ended input to the ADC. The ADC is enabled by writing a '1' to the ADC ENABLE bit in the Control A register (ADCn.CTRLA). Voltage reference and input channel selections will not go into effect before the ADC is enabled. The ADC does not consume power when the ENABLE bit in ADCn.CTRLA is zero.

The ADC generates a 10-bit result that can be read from the Result register (ADCn.RES). The result is presented right adjusted. The result for a 10-bit conversion is given as:

$$RES = \frac{1023 \times V_{IN}}{V_{REF}}$$

where V_{IN} is the voltage on the selected input pin and V_{REF} is the selected voltage reference.

3. ADC Single Conversion

The simplest mode of using the ADC is to make a single conversion. The ADC input pin needs to have the digital input buffer and the pull-up resistor disabled, in order to have the highest possible input impedance. Pin PD6/AIN6 is used for ADC input in this example.

Figure 3-1. ADC0.MUXPOS Selection

Bit	7	6	5	4	3	2	1	0
MUXPOS[4:0]								
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

bits 4:0 MUXPOS[4:0]: MUXPOS bits

This bit field selects which single-ended analog input is connected to the ADC. If these bits are changed during a conversion, the change will not take effect until this conversion is complete.

MUXPOS	Name	Input
0x00-0x0F	AIN0-AIN15	ADC input pin 0 - 15
0x10-0x1B	-	Reserved
0x1C	DACREF0	DAC reference in AC0
0x1D	-	Reserved
0x1E	TEMPSENSE	Temperature Sensor
0x1F	GND	GND
Other	-	Reserved

```
ADC0.MUXPOS = ADC_MUXPOS_AIN6_gc;
```

The ADC Clock Prescaler can be used to divide the clock frequency. In this particular example, the clock is divided by 4. The ADC can use V_{DD}, external reference or internal reference for its positive reference. The internal reference is used in this example.

Figure 3-2. ADC0.CTRLC Voltage Reference Selection

Bit	7	6	5	4	3	2	1	0
		SAMPCAP	REFSEL[1:0]				PRESC[2:0]	
Access	R	R/W	R/W	R/W	R	R/W	R/W	R/W

bits 5:4 REFSEL[1:0]: Reference Selection bits

These bits select the voltage reference for the ADC.

Value	Name	Description
0x0	INTERNAL	Internal reference
0x1	VDD	V_{DD}
0x2	VREFA	External reference V_{REFA}
Other	-	Reserved.

bits 2:0 PRESC[2:0]: Prescaler bits

These bits define the division factor from the Peripheral Clock (CLK_PER) to the ADC Clock (CLK_ADC).

Value	Name	Description
0x0	DIV2	CLK_PER divided by 2
0x1	DIV4	CLK_PER divided by 4
0x2	DIV8	CLK_PER divided by 8
0x3	DIV16	CLK_PER divided by 16
0x4	DIV32	CLK_PER divided by 32
0x5	DIV64	CLK_PER divided by 64
0x6	DIV128	CLK_PER divided by 128
0x7	DIV256	CLK_PER divided by 256

```
ADC0.CTRLC |= ADC_PRESC_DIV4_gc;
ADC0.CTRLC |= ADC_REFSEL_INTREF_gc;
```

The ADC resolution is set by the RESSEL bit in the ADC0.CTRLA register. The ADC is enabled by setting the ENABLE bit in the ADC0.CTRLA register.

Figure 3-3. ADC0.CTRLA Resolution Selection

Bit	7	6	5	4	3	2	1	0
	RUNSTBY					RESSEL	FREERUN	ENABLE
Access	R/W					R/W	R/W	R/W
Reset	0					0	0	0

bit 2 RESSEL: Resolution Selection bit

This bit selects the ADC resolution.

Value	Description
0	Full 10-bit resolution. The 10-bit ADC results are accumulated or stored in the ADC Result register (ADC.RES).
1	8-bit resolution. The conversion results are truncated to eight bits (MSbs) before they are accumulated or stored in the ADC Result register (ADC.RES). The two Least Significant bits are discarded.

bit 0 ENABLE: ADC Enable bit

Value	Description
0	ADC is disabled
1	ADC is enabled

```
ADC0.CTRLA |= ADC_RESSEL_10BIT_gc;
ADC0.CTRLA |= ADC_ENABLE_bm;
```

The ADC conversion is started by setting the STCONV bit in the ADC0.COMMAND register.

Figure 3-4. ADC0.COMMAND - Start conversion

Bit	7	6	5	4	3	2	1	0
							STCONV	
Access								R/W
Reset								0

bit 0 STCONV: Start Conversion bit

Writing a ‘1’ to this bit will start a single measurement. If in Free Running mode this will start the first conversion. STCONV will read as ‘1’ as long as a conversion is in progress. When the conversion is complete, this bit is automatically cleared.

```
ADC0.COMMAND = ADC_STCONV_bm;
```

When the conversion is done, the RESRDY bit in the ADC0.INTFLAGS gets set by the hardware. The user must wait for that bit to get set before reading the ADC result.

Figure 3-5. ADC0.INTFLAGS - hardware-set RESRDY bit

Bit	7	6	5	4	3	2	1	0
Access							WCOMP	RESRDY
Reset							R/W	R/W

bit 0 RESRDY: Result Ready Interrupt Flag bit

The Result Ready Interrupt flag is set when a measurement is complete and a new result is ready. The flag is cleared by either writing a '1' to the bit location or by reading the Result register (ADCn.RES). Writing a '0' to this bit has no effect.

```
while (! (ADC0.INTFLAGS & ADC_RESRDY_bm))  
{  
    ;  
}
```

The user must clear the RESRDY bit by writing '1' to it before starting another conversion.

```
ADC0.INTFLAGS = ADC_RESRDY_bm;
```

The conversion result can be read from the ADC0.RES register.

```
adcVal = ADC0.RES;
```

Click to browse repository

Tip: The full code example is also available in the [Appendix](#) section.

4. ADC Free Running

When configuring the ADC in Free Running mode, the next conversion starts immediately after the previous one completes. To activate this mode, the FREERUN bit in the ADC0.CTRLA must be set in addition to the normal ADC initialization.

Figure 4-1. ADC0.CTRLA - set FREERUN bit

Bit	7	6	5	4	3	2	1	0
	RUNSTBY					RESSEL	FREERUN	ENABLE
Access	R/W					R/W	R/W	R/W
Reset	0					0	0	0

bit 1 FREERUN: Free-Running bit

Writing a ‘1’ to this bit will enable the Free Running mode for the data acquisition. The first conversion is started by writing the STCONV bit in ADC.COMMAND high. In the Free Running mode, a new conversion cycle is started immediately after or as soon as the previous conversion cycle has completed. This is signaled by the RESRDY flag in ADCn.INTFLAGS.

```
ADC0.CTRLA |= ADC_FREERUN_bm;
```

The ADC conversion is started by setting the STCONV bit in the ADC0.COMMAND register:

```
ADC0.COMMAND = ADC_STCONV_bm;
```

Then the ADC results can be read in a `while` loop:

```
while(1)
{
    if (ADC0_conersionDone())
    {
        adcVal = ADC0_read();
    }
}
```

[View Code Example on GitHub](#)
Click to browse repository

Tip: The full code example is also available in the [Appendix](#) section.

5. ADC Sample Accumulator

In Sample Accumulator mode the ADC can add up to 64 samples in an accumulator register, thus filtering the signal and reducing the noise. It is useful when reading analog sensor data where a smooth signal is required. By using a hardware accumulator instead of adding those readings in software, it reduces the CPU load. To activate this mode, the Sample Accumulation Number in the ADC0.CTRLB register must be set in addition to the normal ADC initialization.

Figure 5-1. ADC0.CTRLB - set SAMPNUM bit

Bit	7	6	5	4	3	2	1	0
	SAMPNUM[2:0]							
Access						R/W	R/W	R/W
Reset						0	0	0

bits 2:0 SAMPNUM[2:0]: Sample Accumulation Number Select bits

These bits select how many consecutive ADC sampling results are accumulated automatically. When this bit is written to a value greater than 0x0, the according number of consecutive ADC sampling results are accumulated into the ADC Result register (ADC.RES) in one complete conversion.

Value	Name	Description
0x0	NONE	No accumulation.
0x1	ACC2	2 results accumulated.
0x2	ACC4	4 results accumulated.
0x3	ACC8	8 results accumulated.
0x4	ACC16	16 results accumulated.
0x5	ACC32	32 results accumulated.
0x6	ACC64	64 results accumulated.
0x7	-	Reserved.

```
ADC0.CTRLB = ADC_SAMPNUM_ACC64_gc;
```

The ADC conversion is started by setting the STCONV bit in the ADC0.COMMAND register.

```
ADC0.COMMAND = ADC_STCONV_bm;
```

The samples will be added up in the ADC0.RES register. The ADC_RESRDY flag is set after the number of samples specified in ADC0.CTRLB is acquired.

```
while (! (ADC0.INTFLAGS & ADC_RESRDY_bm))
{
    ;
}
```

The user can read that value and divide it by the number of samples, in order to get an average value.

```
adcVal = ADC0.RES;
adcVal = adcVal >> ADC_SHIFT_DIV64;
```

The user must clear the RESRDY bit by writing '1' to it before starting another conversion.

```
ADC0.INTFLAGS = ADC_RESRDY_bm;
```

Click to browse repository

Tip: The full code example is also available in the [Appendix](#) section.

6. ADC Window Comparator

In Window Comparator mode, the device can detect if the ADC result is below or above a specific threshold value. This is useful when monitoring a signal that is required to be maintained in a specific range, or for signaling low battery/overcharge, etc. The Window Comparator can be used in both Free Running mode and Single Conversion mode. In this example the Window Comparator is used in Free Running mode, because a monitored signal requires continuous sampling, and the Free Running mode reduces the CPU load by not requiring manual start for each conversion.

For this example, a low threshold is set in the ADC0.WINLT register.

Figure 6-1. ADC-WINLT - set Low Threshold

Bit	15	14	13	12	11	10	9	8
WINLT[15:8]								
Access	R/W							
Reset	0	0	0	0	0	0	0	0
WINLT[7:0]								
Access	R/W							
Reset	0	0	0	0	0	0	0	0

bits 15:8 WINLT[15:8]: Window Comparator Low Threshold High Byte

These bits hold the MSB of the 16-bit register.

bits 7:0 WINLT[7:0]: Window Comparator Low Threshold Low Byte

These bits hold the LSB of the 16-bit register.

```
ADC0.WINLT = WINDOW_CMP_LOW_TH_EXAMPLE;
```

The Conversion Window mode is set in the ADC0.CTRLE register:

Figure 6-2. ADC0.CTRLE - set Window Comparator mode

Bit	7	6	5	4	3	2	1	0
WINCM[2:0]								
Access						R/W	R/W	R/W
Reset						0	0	0

bits 2:0 WINCM[2:0]: Window Comparator Mode bits

This field enables and defines when the interrupt flag is set in Window Comparator mode. RESULT is the 16-bit accumulator result. WINLT and WINHT are 16-bit lower threshold value and 16-bit higher threshold value, respectively.

Value	Name	Description
0x0	NONE	No Window Comparison (default)
0x1	BELOW	<i>RESULT < WINLT</i>
0x2	ABOVE	<i>RESULT > WINHT</i>
0x3	INSIDE	<i>WINLT < RESULT < WINHT</i>
0x4	OUTSIDE	<i>RESULT < WINLT or RESULT > WINHT</i>
Other	-	Reserved

```
ADC0.CTRLE = ADC_WINCM_BELOW_gc;
```

If the ADC result is below the set threshold value, the WCOMP bit in the ADC0.INTFLAGS register is set by the hardware.

Figure 6-3. ADC0.INTFLAGS - hardware-set WCOMP bit

Bit	7	6	5	4	3	2	1	0
							WCOMP	RESRDY
Access							R/W	R/W
Reset							0	0

bit 1 WCOMP: Window Comparator Interrupt Flag bit

This Window Comparator flag is set when the measurement is complete and if the result matches the selected Window Comparator mode defined by WINCM (ADCn.CTRLE). The comparison is done at the end of the conversion. The flag is cleared by either writing a '1' to the bit position or by reading the Result register (ADCn.RES). Writing a '0' to this bit has no effect.

The user must clear that bit by writing '1' to it.

```
ADC0.INTFLAGS = ADC_WCMP_bm;
```

[View Code Example on GitHub](#)
Click to browse repository

 **Tip:** The full code example is also available in the [Appendix](#) section.

7. ADC Event Triggered

An ADC conversion can be triggered by an event. This is enabled by writing a '1' to the Start Event Input bit (STARTEI) in the Event Control register (ADCn.EVCTRL).

Figure 7-1. ADC0.EVTRL - enable STARTEI bit

Bit	7	6	5	4	3	2	1	0	STARTEI
Access									R/W
Reset									0

bit 0 STARTEI: Start Event Input bit

This bit enables using the event input as trigger for starting a conversion.

```
ADC0.EVCTRL |= ADC_STARTEI_bm;
```

Any incoming event routed to the ADC through the Event System (EVSYS) will trigger an ADC conversion. The event trigger input is edge sensitive. When an event occurs, STCONV in ADCn.COMMAND is set. STCONV will be cleared when the conversion is complete.

For example, to start the ADC conversion on RTC overflow, the following settings must be made:

1. The RTC overflow event must be linked to channel 0 of the Event System
2. The Event User ADC0 must be configured to take its input from channel 0
3. The STARTEI bit in the EVCTRL register of the ADC must be set to enable the ADC conversion to be triggered by events

```
EVSYS.CHANNEL0 = EVSYS_GENERATOR_RTC_OVF_gc; /* Real Time Counter overflow */  
EVSYS.USERADC0 = EVSYS_CHANNEL_CHANNEL0_gc; /* Connect user to event channel 0 */  
ADC0.EVCTRL |= ADC_STARTEI_bm; /* Enable event triggered conversion */
```

The Microchip Web Site

Microchip provides online support via our web site at <http://www.microchip.com/>. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

Customer Change Notification Service

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at <http://www.microchip.com/>. Under "Support", click on "Customer Change Notification" and follow the registration instructions.

Customer Support

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: <http://www.microchip.com/support>

Microchip Devices Code Protection Feature

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.

- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Quality Management System Certified by DNV

ISO/TS 16949

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
